

Neuropsychometry is a type of assessment used to evaluate various cognitive functions, including memory, attention, language, perception, and executive function. The assessment is carried out by a trained neuropsychologist or clinical psychologist who uses a battery of tests to evaluate the patient's cognitive strengths and weaknesses.

The assessment typically involves an interview to gather information about the patient's medical history and symptoms, followed by a series of standardised tests. The tests may include paper-and-pencil tasks, computer-based tests, and other measures of cognitive function.

The tests are not pass/fail, they are designed to test the limits of an individual's cognitive function in a particular cognitive domain.

During the appointment, the psychologist will explain the testing procedures and answer any questions the patient may have. The testing may take several hours or be spread over several sessions, depending on the complexity of the evaluation. Patients may be asked to bring a family member or friend who can provide additional information about their cognitive functioning.

After the assessment is complete, the psychologist will provide a detailed report of the findings, including strengths and weaknesses, and recommendations for treatment and further evaluation if necessary.

The results of the neuropsychometric evaluation can help guide treatment planning and provide important information for the patient and their healthcare team.
